

LO is an exact delta function at $p_T^{t\bar{t}} = 0$ (all 100000/100000 LO events, back-to-back 2->2 kinematics): first-bin (0-10 GeV) entry only, $d\sigma/dp_T$=51.9852 pb/GeV (=$\sigma_{LO}$/binwidth). NLO shows a genuine nonzero tail from real QCD emission. Ratio panel omitted (LO is a delta function, ratio undefined). NLO bin 10-20 GeV is negative (-0.885+/-0.091 pb/GeV, f_minus=0.56) -- a known fixed-order-NLO feature immediately next to the Born (pT->0) boundary from incomplete real/virtual cancellation, not a bug; omitted from the log-scale line as a gap.
